
Three dimensional coordinates into two dimensional coordinates transformation

Edward Gerhold

June 27, 2015

Version 0.1.5 (very drafty paper)

The formulas are correct. But the text itself is in the first stage. And i have to learn L^AT_EX for the first time.

June 25, 2015

Remark On a piece of paper you see three coordinate axis pointing into three directions in space. In reality these vectors are two dimensional. Because they point into three directions on the paper, and not into the real space.

[Picture of a 3-D coordinate system with ijk-vectors on the axis pointing into three Directions]

In this document we will design a basis for the coordinate transformation. A basis is multiplied with the value of the coordinate to move to the correct new point.

In the case of cosines and sines, we move left and right and up and down, to tell you directly, what happens, when we multiply the coordinates with the matrix.

The quick overview may move to the back as summarization.

Quick overview

1. Lay out the three base vectors around a circle and write down the angles φ_n .
2. Write down the base vectors \vec{e}_n as $\cos \varphi$ and $\sin \varphi$ (two dimensional) with a unit length of 1, or multiplied with $r_n \neq 1$.
3. Put the three base vectors \vec{e}_n into a matrix A. Programmers can directly code the two lines multiplication and forget the formal rest.
4. Iterate over your points and multiply each (x, y, z) with the linear operator, the matrix A, and put (x', y') into your new set.

1 Definitions

Definition Let φ_n be the set of axis angles, one for each axis. The angles start at the same place, at the number zero. You have to arrange the x , y , and z axes like on a piece of paper around the unit circle by giving them the appropriate angles. All three angles start at the default at zero.

$$\varphi_n := \{\varphi_x, \varphi_y, \varphi_z\}$$

Example The function rad converts degrees to radians, its useful for computer functions taking radians.

$$\text{rad}\phi := \frac{\pi}{180} \times \phi, \phi$$

Here is an example of three angles. The three axis have an angle of 120 degrees between each.

$$\varphi_x = \text{rad}210, \varphi_y = \text{rad}330, \varphi_z = \text{rad}90$$

Definition Let e_n be the set of three two dimensional unit base vectors, namely \vec{e}_x, \vec{e}_y and e_z . Other names are i, j or k for example, like on the picture of the coordinate system mentioned. The three vectors point into the three directions of the three axis. On a piece of paper they are two dimensional, because they point into three directions on the paper. The space being shown is what our brain completes, seeing three correct axis. The three base vectors represent exactly one unit of each axis.

$$e_n := \{\vec{e}_x, \vec{e}_y, \vec{e}_z\}$$

This is the set of three unit vectors in set notation. To guess no numbers, its easier for us, for each vector, to go around the unit circle by the angles we already defined and to use cosine and sine for the correct x -distance and y -distance. For help, you should remember this parametrization of x and y from the unit circle.

$$\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} r \cos \varphi \\ r \sin \varphi \end{pmatrix}$$

$$(x, y) = (r \cos \varphi, r \sin \varphi)$$

Definition

Modeling the three two dimensional base vectors with this information, we get the following three two dimensional base vectors.

$$\vec{e}_x := (r_x \cos(\varphi_x), r_x \sin(\varphi_x))^T = \begin{pmatrix} r_x \cos(\varphi_x) \\ r_x \sin(\varphi_x) \end{pmatrix}$$

$$\vec{e}_y := (r_y \cos(\varphi_y), r_y \sin(\varphi_y))^T = \begin{pmatrix} r_y \cos(\varphi_y) \\ r_y \sin(\varphi_y) \end{pmatrix}$$

$$\vec{e}_z := (r_z \cos(\varphi_z), r_z \sin(\varphi_z))^T = \begin{pmatrix} r_z \cos(\varphi_z) \\ r_z \sin(\varphi_z) \end{pmatrix}$$

One for each component of (x, y, z) By multiplying with, we move the points into the right pieces of direction. On the plane we use to point into three directions.

Remark. The values of r_x, r_y and r_z decide, how long one unit into each direction is. To preserve affine graphical transformations all three axes should have the same unit length, which can generally be enlarged or made smaller than unit length. By default the resulting vector of the cos and sin Terms has unit length, if you dont multiply with r_x, r_y and r_z .

[here is a jump in the text, but it has to be rewritten anyways]

The other help we take The other lemma we need is the theorem for multiplying with the orthogonal bases. The sum of the basis multiplied with the coordinates is nothing new. But Literature and lecture scripts just tell how to multiply same dimensions, giving no clue about the easy 3-D to 2-D conversions.

$$\vec{v} = \sum_n \vec{e}_n \vec{x}_n$$

Each (x, y, z) coordinate has to be multiplied for the new (x', y') with its corresponding term of the unit vectors in the matrix. That means, to sum the products with (x, y, z) and the cos terms up for x' and to sum the products of

(x, y, z) and the sin terms up for y' . This is the same as imagining walking left and right with $\cos \varphi$ and up and down with $\sin \varphi$. Or mathematically adding positive or negative values.

$$\begin{pmatrix} x' \\ y' \end{pmatrix} = \begin{pmatrix} xr_x \cos(\varphi_x) + yr_y \cos(\varphi_y) + zr_z \cos(\varphi_z) \\ xr_x \sin(\varphi_x) + yr_y \sin(\varphi_y) + zr_z \sin(\varphi_z) \end{pmatrix}$$

Definition Let A be the matrix containing the three two dimensional unit vectors in order, one each column. You get a 2x3 matrix $A :^3 \rightarrow ^2$.¹ With the base vectors $\begin{pmatrix} \cos \varphi_n \\ \sin \varphi_n \end{pmatrix}$ in the three columns.

$$A := (\vec{e}_x \quad \vec{e}_y \quad \vec{e}_z) = \begin{pmatrix} r_x \cos(\varphi_x) & r_y \cos(\varphi_y) & r_z \cos(\varphi_z) \\ r_x \sin(\varphi_x) & r_y \sin(\varphi_y) & r_z \sin(\varphi_z) \end{pmatrix}$$

2 Theorem

Theorem (*Fundamental Theorem of converting 3-D Points into 2-D Points*):

If you multiply A, the matrix of the three two-dimensional unit vectors, with the three-coordinate points (x, y, z) , the result is a two coordinate point, (x', y') . This point (x', y') is the correct point on the two dimensional plane, representing the point from the three dimensional coordinate system, we would like to display.

$$A \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} x' \\ y' \end{pmatrix}$$

Applying the operator² performs the following operation

$$\begin{aligned} A \begin{pmatrix} x \\ y \\ z \end{pmatrix} &= x\vec{e}_x + y\vec{e}_y + z\vec{e}_z \\ &= \begin{pmatrix} xr_x \cos(\varphi_x) + yr_y \cos(\varphi_y) + zr_z \cos(\varphi_z) \\ xr_x \sin(\varphi_x) + yr_y \sin(\varphi_y) + zr_z \sin(\varphi_z) \end{pmatrix} = \begin{pmatrix} x' \\ y' \end{pmatrix} \end{aligned}$$

Proof

$$A \begin{pmatrix} x \\ y \\ z \end{pmatrix} = x\vec{e}_x + y\vec{e}_y + z\vec{e}_z = \begin{pmatrix} x' \\ y' \end{pmatrix}$$

¹A 2x3 Matrix, which i call the Gerhold Projection Matrix to distinguish it from other matrices, making sure it contains the three two dimensional base vectors. for each of source coordinate components inside.

²The *Gerholdian* operator is my favorite nickname for this matrix

$$\begin{pmatrix} x' \\ y' \end{pmatrix} = \begin{pmatrix} xr_x \cos(\varphi_x) + yr_y \cos(\varphi_y) + zr_z \cos(\varphi_z) \\ xr_x \sin(\varphi_x) + yr_y \sin(\varphi_y) + zr_z \sin(\varphi_z) \end{pmatrix}$$

Example

The following is an EcmaScript 6 (JavaScript) Arrow Function returning the new point. It is not optimized for speed. Means, to repeat the sin and cosine calls.

Example for Programmers `let projection = ([x,y,z]) => [x*r*Math.cos(xAxisAngle) + y*r*Math.cos(yAxisAngle) + z*r*Math.cos(zAxisAngle), x*r*Math.sin(xAxisAngle) + y*r*Math.sin(yAxisAngle) + z*r*Math.sin(zAxisAngle)]`

3 Corollary

The theorem can be extended into more dimension to go down to any other dimension. The generic case is known to linear algebra, i found it lately after beginning this document and will include the information within the next versions.

Corollary (*Converting any Dimensions down to less dimensions*):

The theorem can be extended to more dimensions, for example can four two-dimensional vectors represent a 4-D space on the 2-D plane. They get converted into the correct 2-D points. For Example, if you use a 2x4 matrix and convert all points at each instance of t you have a moving object into the direction of the fourth base vector.

$$A := \begin{pmatrix} \vec{e}_x & \vec{e}_y & \vec{e}_z & \vec{e}_t \end{pmatrix} = \begin{pmatrix} r_x \cos(\varphi_x) & r_y \cos(\varphi_y) & r_z \cos(\varphi_z) & r_t \cos(\varphi_t) \\ r_x \sin(\varphi_x) & r_y \sin(\varphi_y) & r_z \sin(\varphi_z) & r_t \sin(\varphi_t) \end{pmatrix}$$

Here the basis is four times of two dimensions. A 2x4 matrix.

$$A \begin{pmatrix} x \\ y \\ z \\ t \end{pmatrix} = \sum_n \vec{e}_n \vec{x}_n = \begin{pmatrix} x' \\ y' \end{pmatrix}$$

Proof:

$$A \begin{pmatrix} x \\ y \\ z \\ t \end{pmatrix} = \begin{pmatrix} xr_x \cos(\varphi_x) + yr_y \cos(\varphi_y) + zr_z \cos(\varphi_z) + tr_t \cos(\varphi_t) \\ xr_x \sin(\varphi_x) + yr_y \sin(\varphi_y) + zr_z \sin(\varphi_z) + tr_t \sin(\varphi_t) \end{pmatrix}$$

$$= x\vec{e}_x + y\vec{e}_y + z\vec{e}_z + t\vec{e}_t = \sum_n \vec{e}_n \vec{x}_n = \begin{pmatrix} x' \\ y' \end{pmatrix}$$

The same method can be used to convert any other number of dimensions to the xy -plane. If you know the base vectors for the other dimensions you can convert down to other dimensions as well.
